Introduction

We have been experimenting with using counting boards of different sizes as a platform for teaching the arithmetic of rational numbers in elementary and middle grades.

60	 20	12	4
30	10	 6	2
15	5	3	 1

 1	 $\frac{1}{3}$	$\frac{1}{5}$	$\frac{1}{15}$
$\frac{1}{2}$	$\frac{1}{6}$	$\frac{1}{10}$	$\frac{1}{30}$
$\frac{1}{4}$	$\frac{1}{12}$	$\frac{1}{20}$	$\frac{1}{60}$

The values of locations in any column *always* form a geometric progression with quotient 2.

Tokens are of two colors. White tokens have the value 1 and red tokens have the value -1. So the three tokens on the first board represent the number $15 = 20 + -6 + 1$, and the two tokens on the second board represent the value $\frac{2}{3} = 1 - \frac{1}{3}$.

Representing numbers on boards, instead of writing them down, has the following advantages.

1. Students can carry out fairly complex computations before they master “number facts”.
2. Good penmanship is not required.
3. Only very limited knowledge of number-words is necessary. And this feature is important in multi-lingual classrooms.

Addition and subtraction of fractions whose denominators are factors of 60

On the fraction board we have a number, $\frac{1}{2} - \frac{1}{3} + \frac{1}{4} - \frac{1}{5}$.
To compute the total we put the same configuration of tokens on the integer board.

Now we regroup these tokens, getting $30 - 20 + 15 - 12 = 10 + 3 = 13$.

$$10 + 3 = 13$$

We copy this onto the fraction board:

This configuration on the fraction board means that

$$\frac{1}{2} - \frac{1}{3} + \frac{1}{4} - \frac{1}{5} = \frac{1}{6} + \frac{1}{20} = \frac{13}{60}$$

This method of computation is justified by distributivity of multiplication. The values on the integer board are the values from fraction board multiplied by 60.

The size of the board that is used depends on the range of dominators we want to handle.

Computing with denominators that contain many prime factors requires fairly large boards and more advanced techniques.

Other examples

The boards have been used for three different purposes:

- (1) To teach standard algorithms for addition, subtraction, multiplication, and division
- (2) To do hands-on tasks whose completion requires complex arithmetic computations, without using calculators or computers
- (3) To investigate properties of rational numbers

Very few students (preservice teachers and elementary/middle school pupils) have shown interested in activities involving standard algorithms.

Hands-on activities were interesting for most students from all backgrounds.

Even college students seem to prefer mathematical problems that arise from meaningful physical activities.

Investigations of properties of rational numbers have been the most popular. They are not time consuming; they are interesting to most students, and often produce surprising and unexpected results.

An example

In how many ways can you represent the number 3 on a specific board using only two tokens? (You may use negative numbers and fractions.)

60	20	12	4
30	10	6	2
15	5	3	1

1	$\frac{1}{3}$	$\frac{1}{5}$	$\frac{1}{15}$
$\frac{1}{2}$	$\frac{1}{6}$	$\frac{1}{10}$	$\frac{1}{30}$
$\frac{1}{4}$	$\frac{1}{12}$	$\frac{1}{20}$	$\frac{1}{60}$

Adding fractions, as we have shown above, is a rather advanced topic in elementary and middle grades.

But the same two boards have also been used with young learners for telling time.

When they put the number of minutes on the integer board, the same configuration of tokens on the fraction board shows the same length of time as a fraction of an hour.
